

SGM48211 120V Boot, 4A Peak, High Frequency High-side and Low-side Driver

GENERAL DESCRIPTION

The SGM48211 is a half-bridge MOSFET driver with 4A peak source and sink output current capability, which makes it possible to drive large power MOSFETs with minimized switching losses. The two channels of high-side and low-side are totally independent with 3ns (TYP) delay matching between the turn-on and turn-off of each other.

The maximum withstanding voltage of the input stage of SMG48211 is 20V. Due to the $-10V_{DC}$ voltage endurance capacity of its input stage, the driver has enhanced robustness and can be interfaced to pulse transformers directly without using rectifier diodes. With a wide input hysteresis, the device can receive analog or digital PWM signals with improved noise immunity.

A 120V rated bootstrap diode is integrated internally to save the external diode and reduce PCB dimension size.

Under-voltage lockout (UVLO) is integrated in both the high-side and the low-side drivers. The output of each channel is forced low if the corresponding driving voltage falls below the specified threshold.

The SGM48211 is available in Green SOIC-8, SOIC-8 (Exposed Pad) and TDFN-4×4-8AL packages.

FEATURES

- Wide Operating Range: 8V to 17V
- Drive Two N-MOSFETs Configured in Half Bridge
- Maximum Blocking Voltage: 120V DC
- Integrated Internal Bootstrap Diode for Cost Saving
- 4A Peak Sink and Source Currents
- -10V to 20V Tolerance of Input Pins
- COMS/TTL Compatible Inputs
- 6.5ns (TYP) Rise Time and 4.7ns (TYP) Fall Time with 1000pF Load
- Propagation Delay Time: 31ns (TYP)
- Delay Matching: 3ns (TYP)
- UVLO Functions for Both High-side and Low-side Drivers
- -40°C to +140°C Operating Temperature Range
- Available in Green SOIC-8, SOIC-8 (Exposed Pad) and TDFN-4×4-8AL Packages

APPLICATIONS

Power Converters in 48V or Lower Systems Used in Telecom, Datacom, Portable Storage, etc. Half-Bridge, Full-Bridge, Push-Pull, Synchronous-Buck and Forward Converters Synchronous Rectifiers Class-D Audio Amplifiers

HS Voltage Slew Rate	50V/ns (MAX)
Operating Junction Temperature Range	40°C to +140°C

OVERSTRESS CAUTION

Stresses beyond those listed in Absolute Maximum Ratings may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect reliability. Functional operation of the device at any conditions beyond those indicated in the Recommended Operating Conditions section is not implied.

ESD SENSITIVITY CAUTION

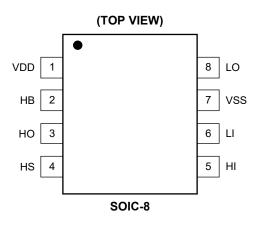

This integrated circuit can be damaged if ESD protections are not considered carefully. SGMICRO recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage. ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because even small parametric changes could cause the device not to meet the published specifications.

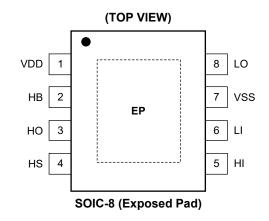

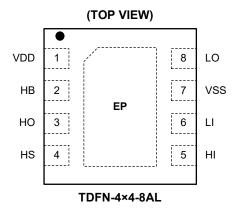

SGM48211

120V Boot, 4A Peak, High Frequency High-side and Low-side Driver

PIN CONFIGURATIONS

PIN DESCRIPTION

PIN	NAME	I/O	FUNCTION
1	VDD	Р	Positive Supply of the Whole Driver. A decoupling capacitor in the range of 0.22 μ F to 4.7 μ F is connected between VDD and VSS pins. ⁽¹⁾
2	HB	Р	High-side Bootstrap Supply. A bootstrap capacitor in the range of 0.022µF to 0.1µF is connected between HB and HS pins. The capacitor value varies with total gate charge of external MOSFET, the switching speed, as well as the voltage ripple criteria.
3	НО	0	Output of the High-side Driver. Connect this pin to the gate of the high-side MOSFET.
4	HS	Ρ	Reference Ground of the High-side Output Stage. Tie this pin directly to the source of external high-side power MOSFET.
5	HI	Ι	Input of the High-side Driver. ⁽²⁾
6	LI	I	Input of the Low-side Driver. (2)
7	VSS		Reference Ground of the Device.
8	LO	0	Output of the Low-side Driver. Connect this pin to the gate of the low-side MOSFET.
Exposed Pad ⁽³⁾	—	_	Thermal Pad. Connect directly to VSS with a large wide trace or polygon copper to achieve improved thermal conduction.

NOTES:

1. It is recommended to use the upper capacitance range for low temperature consideration.

2. Capacitors with typical value of 1nF to 10nF are recommended to be placed between HI/LI and VSS pins, which will be a great help to filter noise presented on these pins.

3. The exposed pad is internally connected to the substrate for thermal conduction and should be connected to the ground outside.

TYPICAL APPLICATION CIRCUIT

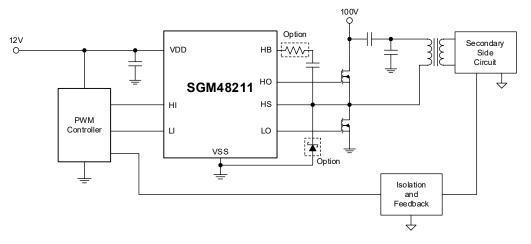

Figure 1. Typical Application Diagram

The capacitance value of the bootstrap capacitor is recommended to be less than 680nF to prevent excessive transient current breakdown of the bootstrap diode when charging the bootstrap capacitor.

If the Q_G of the power transistor is particularly large and requires a capacitor greater than 680nF, a resistor can be directly connected in series with bootstrap capacitor at the HB pin to reduce the transient current. A 1 Ω to 2Ω series resistance is recommended. It is also important to note that this series resistance also increases the total turn-on resistance.

A Schottky diode is recommended to clamp the HS voltage slightly lower than V_{SS} during large di/dt as shown in the dashed box in Figure 1. Connect the diode between HS pin and VSS pin directly and tie the cathode of the diode to HS pin. Its minimum blocking voltage should be larger than the maximum positive voltage of the half bridge.

ELECTRICAL CHARACTERISTICS

 $(V_{DD} = V_{HB} = 12V, V_{HS} = V_{SS} = 0V$, no load on LO or HO, $T_A = T_J = -40^{\circ}C$ to +140°C, typical values are at $T_A = T_J = +25^{\circ}C$, unless otherwise noted.)

SGM48211

FUNCTIONAL BLOCK DIAGRAM

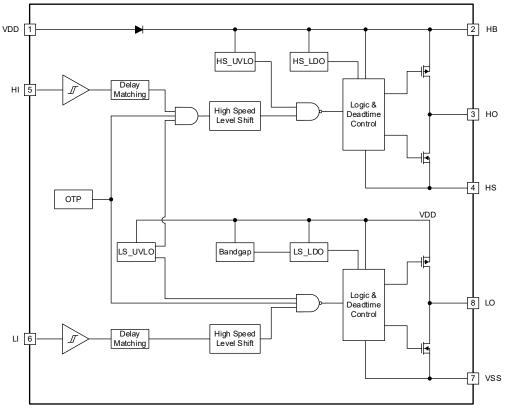

Figure 3. Functional Block Diagram

DETAILED DESCRIPTION

The SGM48211 is a high-side and low-side gate driver and is designed to drive two switches in a half-bridge configuration. Highlights of the SGM48211 are listed in Table 1. Due to the combination of these features, the device can operate with high frequency and robustness.

Table 1. Prominent Features and Benefits

FEATURE	BENEFIT		
4A peak source and sink current	To drive large power MOSFET and minimum switching losses.		
Wide input withstanding voltage range of -10V to 20V V_{DC}	High robustness and reliability. Can be used in various applications.		
120V internal bootstrap diode	Large margin to meet telecom 100V surge requirements and reduce system cost.		
Robust ESD circuitry	Improved immunity to Common Mode (CM) and Differential Mode (DM) noises.		
31ns (TYP) propagation delay	Low current distortion.		
3ns (TYP) delay matching between channels	Better Symmetry of Positive and Negative waveform.		
Both high-side and low-side drivers feature UVLO circuit	Ensures two channels shutdown simultaneously.		
CMOS/TTL optimized thresholds with wide voltage hysteresis	Improved noise immunity.		

Input Stage

The input of each channel is designed with $68k\Omega$ input impedance (internal pull-down to VSS). The input stages of the SGM48211 are CMOS/TTL compatible and designed with 2.25V logic high and 1.55V logic low thresholds, $68k\Omega$ equivalent input impedance. A $68k\Omega$ pull-down resistor is integrated internally in each channel.

Output Stage

Both output stages of the two drivers are designed to source and sink 4A peak current. Thus it allows for driving MOSFETs with high current capability and low switching losses. VSS is the reference ground of the low-side output stage and HS is the reference ground of the high-side output stage.

Under-Voltage Lockout (UVLO)

UVLO protections are implemented in both bias supplies of the high-side and low-side drivers. Once triggered, the V_{DD} UVLO disables both drivers while the V_{HB} UVLO only disables the high-side driver. The rising UVLO thresholds of V_{DD} and V_{HB} are 7V with 0.5V hysteresis and 6.4V with 1V hysteresis respectively.

Level Shift

A level shift circuit is integrated to shift the input signal to the output stage of the high-side driver and provides the minimum delay matching with the low-side driver.

Bootstrap Diode

A 120V rated bootstrap diode is internally connected between VDD and HB pins of the SGM48211 for generating the high-side bias. During turn-on of the low-side MOSFET in each cycle, the capacitor connected between the HB and HS pins is charged from VDD to HS through the bootstrap diode which provides fast recovery time and low diode resistance for efficient operation.

Device Functional Modes

When the SGM48211 operates in normal mode (inactive UVLO), the outputs (HO and LO) of both drivers follow their corresponding input signals (HI and LI) as listed in Table 2.

Table 2. Device Logic Table

HI Pin	LI Pin	HO Pin ⁽¹⁾	LO Pin ⁽²⁾
L	L	L	L
L	Н	L	н
н	L	н	L
Н	Н	Н	Н

NOTES:

1. With reference to HS.

2. With reference to VSS.

APPLICATION INFORMATION

The SGM48211 implements both the level-shifting and buffer-drive functions to boost the 3.3V signal to the gate-drive voltage to fully turn on the power device for achieving high-frequency switching, minimizing noise and controlling floating power-device gates and reducing power losses.

The SGM48211 is designed with low propagation delays and adopts low-inductance and compact package. It is available to drive wide band-gap power device such as GaN based switches for supporting very high switching frequency and low-cost component count.

Design Requirements Table 3. Design Specifications

Design Parameter	Example Value	
Supply Voltage, V _{DD}	12V	
Voltage on HS, V _{HS}	0V to 100V	
Voltage on HB, V _{HB}	12V to 112V	
Output Current Rating, Io	-4A to 4A	
Operating Frequency	500kHz	

Input Threshold Type

The SGM48211 can handle a maximum input voltage range from -10V to 20V to achieve enhanced robustness and allow compatibility with both inputs from microcontrollers, as well as higher-voltage inputs from gate-drive transformers. The inputs adopt TTL and CMOS compatible structure with a wide range of hysteresis. The voltage threshold is independent of V_{DD} .

Supply Voltage V_{DD}

The SGM48211 operates with a wide supply voltage range from 8V to 17V for applications such as driving Si MOSFETs, IGBTs, SiC MOSFETs and GaN FETs. The maximum voltage on VDD when applied to a single-ended power, and the differential voltage of the positive voltage and the negative voltage when applied to dual-railed power, as well as the bias supply voltage on the VDD pin should never exceed the values listed in the Absolute Maximum Ratings section.

Peak Driving Currents

The SGM48211 is designed with 4A peak source and sink currents for fast switching of power devices. For

example, when the SGM48211 is used to drive an IPB60R120P7 power MOSFET with a DC bus voltage of 400V in a continuous conduction mode (CCM) PFC converter, the turn-on event and the turn-off event are supposed to be completed in approximately 14ns and 8ns (refer to DS of IPB60R120P7 with typical 36nC of total Q_G) separately. Therefore, a source current of 2.57A (= 36nC/14ns) and a sink current of 4.5A (= 36nC/8ns) or higher are necessary. The SGM48211 can provide 4A peak source current and sink currents larger than the requirements of IPB60R120P7.

In practical designs, the parasitic inductance of PCB traces will limit the di/dt of the gate driving current that may not reach the full peak current capability of the driver. To minimize this impact caused by the parasitic inductance, it is recommended to place the gate drive device as close to the power MOSFET as possible and design a tight gate driving loop with minimum parasitic inductance.

External gate resistors for turn-on and turn-off of the MOSFETs should be chosen carefully to achieve efficiency and EMI optimizations.

Propagation Delay

The SGM48211 features 31ns (TYP) propagation delay and 3ns (TYP) delay matching between the high-side and the low-side drivers, which make it possible for the device to operate in very high frequency with little pulse distortion.

Power Dissipation

Power dissipation is the sum of conduction loss and switching loss as shown in Equation 1.

$$P_{\text{DISS}} = P_{\text{DC}} + P_{\text{SW}} \tag{1}$$

where P_{DC} is the conduction loss and can be calculated by Equation 2.

$$\mathsf{P}_{\mathsf{DC}} = \mathsf{I}_{\mathsf{Q}} \times \mathsf{V}_{\mathsf{DD}} \tag{2}$$

where

 I_Q is the total quiescent current consumed by all internal block circuits and internal parasitic devices during switching (such as charging and discharging).

 V_{DD} is the voltage between the VDD and VSS pins.

APPLICATION INFORMATION (continued)

 $\mathsf{P}_{\mathsf{G}}\left(\mathsf{P}_{\mathsf{SW}}\right)$ is the switching loss which can be calculated by Equation 3.

$$P_{G} = Q_{G} \times V_{DD} \times f_{SW}$$
(3)

where

 f_{SW} is the switching frequency.

 Q_G is the total gate charge of the MOSFET, typical 36nC of IPB60R120P7 in this example.

Half of P_G is dissipated during turn-on, and the other half is dissipated by both the external gate resistors and the internal resistance of the SGM48211 during turn-off.

When no external gate resistors are used, P_G is completely dissipated inside the device.

When using external gate resistors, the effective P_{G_PK} dissipated inside the package can be calculated by Equation 4.

$$P_{G_{PK}} = P_{G} \times \left(\frac{R_{IN_{ON}}}{R_{IN_{ON}} + R_{EX_{ON}}} + \frac{R_{IN_{OFF}}}{R_{IN_{OFF}} + R_{EX_{OFF}}}\right)$$
(4)

where

 R_{IN_ON} is the effective pull-up resistance of the output stage of SGM48211.

 $R_{\text{EX_ON}}$ is the total external turn-on resistance of gate resistor and internal gate resistance of the power MOSFET.

 R_{IN_OFF} is the effective pull-down resistance of the output stage of SGM48211.

 $R_{\text{EX_OFF}}$ is the total external turn-off resistance of gate resistor and internal gate resistance of the power MOSFET.

Power Supply Recommendations

The SGM48211 operates in normal mode from the minimum 8V bias supply governed by the UVLO function to the maximum 17V bias supply limited by the 20V absolute maximum voltage with a 3V margin to allow for transient voltage spikes during switching.

UVLO functions are implemented in both V_{DD} and V_{HB} with a hysteresis function. The voltage thresholds of the

UVLOs are typical 7V on V_{DD} - V_{SS} and 6.4V on V_{HB} - V_{HS} with respective 0.5V and 1V hysteresis.

To avoid from entering the UVLO mode caused by the voltage ripple lower than the hysteresis on both V_{DD} and V_{HB} during switching, local bypass capacitors must be placed between the VDD and VSS pins and between the HB and HS pins as close to the device as possible. Low-ESR, ceramic surface-mount capacitors with capacitance in the range of 0.22µF to 4.7µF between VDD and VSS pins and 0.022µF to 0.1µF between HB and HS pins are recommended.

Layout Guidelines

The following layout recommendations should be considered:

- Place the SGM48211 as close to the MOSFETs as possible.
- Locate the bootstrap capacitor (V_{HB} V_{HS}) and decoupling capacitor (V_{DD} V_{SS}) as close to the device as possible.

• Minimize the gate drive loops from the output pins to the gate of MOSFETs. Tie the HS and VSS pins directly to the corresponding source of MOSFETs in short distance.

• Exposed pad should be connected to VSS net and with large polygon copper for improved thermal conduction.

• VDD traces should be away from the high-side pins and the LO pin.

• A minimum width of 60mils is recommended for the HO and LO traces.

• Two or more vias should be used if routing through different layers and for thermal conduction on VSS net.

• Input traces of HI and LI should be away from traces with higher dV/dt.

Thermal Considerations

Measures that reduce the effective thermal resistances from the package to PCB or to the open air should be taken to keep the junction temperature within rated limits.
